

Incident Response

Incident response proceeds through phases: preparation, detection, containment, eradication, and recovery. Each phase has defined outputs that feed the next.

Detection relies on monitoring. Logs from endpoints, network devices, and services feed a detection system that alerts on anomalies.

Containment limits the spread of a compromise. Isolating affected systems and revoking credentials stops lateral movement while investigators preserve evidence.

The response process itself must be practiced. Tabletop exercises reveal gaps in the plan, and post-incident reviews turn failures into durable improvements.
